

Economic events across global cash equity sessions

Question: how do open markets respond, and what is observed when closed markets subsequently reopen?

Hong Kong: Hang Seng (^HSI)

Europe: EURO STOXX 50 (^STOXX50E)

U.S.: Nasdaq-100 cash index (^NDX)

Three cash indices; no NQ=F futures.

Sessions overlap; they do not cover 24h.

DST, lunch breaks and holidays matter.

Europe: main cash-session proxy;
index dissemination is a different window.

Verified against HKEX / Nasdaq hours; XPAR and XNYS are documented calendar proxies.

From the question to a SQL-backed event study

Actual observations | 2024-10-08 to 2024-12-30 | Original Yahoo Finance / Investing.com source flow retained

Yahoo cash-index OHLC + Investing.com economic calendar archive

-> explicit timezone / trading-calendar checks -> SQLite or MySQL -> session-aware reports

1,024 accepted hourly bars | 124 timed high-importance events | 8,928 response attempts

SQL tables: prices, events, market_bars, market_sessions, event_details, pipeline_runs.

Open at release: reference = announcement time; baseline = an already observed price.

Closed at release: reference = next opening; baseline = last observed pre-release close.

Targets in closed sessions are missing. Full hourly bars crossing boundaries are excluded.

Actual reference, baseline age, observed time, elapsed time and co-releases are recorded.

Inputs are local archives / downloads; published results are derived summaries.

UTC calendar timestamps spot-checked against BLS CPI/payrolls and Federal Reserve release times.

Observed results: responses depend on the session

REAL DATA | Descriptive observations, not isolated causal effects | Counts differ across releases and horizons

CPI (MoM): nominal +1h summary

HSI: -0.797% mean (n=3); reopen

NDX: +0.336% mean (n=3); reopen

STOXX50E: -0.184% mean (n=3); release

Reopening returns include other overnight news.

Small samples, co-releases, and hourly resolution limit inference.
